

Analysis of Shallow Water Wave Measurements Recorded at the Field Research Facility

Marios Christou, Dirk Rijnsdorp & Kevin Ewans
Royal Dutch Shell
TU Delft

Friday 4th November 2011

Motivation of Study

- ▶ Part of the NOPP project funded by ONR

Motivation of Study

- ▶ Part of the NOPP project funded by ONR
- ▶ Wave height with given return period is required for designing coastal structures
 - ▶ Wave height probability distribution

Motivation of Study

- ▶ Part of the NOPP project funded by ONR
- ▶ Wave height with given return period is required for designing coastal structures
 - ▶ Wave height probability distribution
- ▶ Hindcast data is typically available in deep water but not shallow depths.
 - ▶ Evolution of frequency spectrum

Motivation of Study

- ▶ Part of the NOPP project funded by ONR
- ▶ Wave height with given return period is required for designing coastal structures
 - ▶ Wave height probability distribution
- ▶ Hindcast data is typically available in deep water but not shallow depths.
 - ▶ Evolution of frequency spectrum
- ▶ Low-frequency waves cause erosion, excite harbour seiches, break ice shelves & cause resonance of moored vessels
 - ▶ Infragravity wave prediction

Methodology

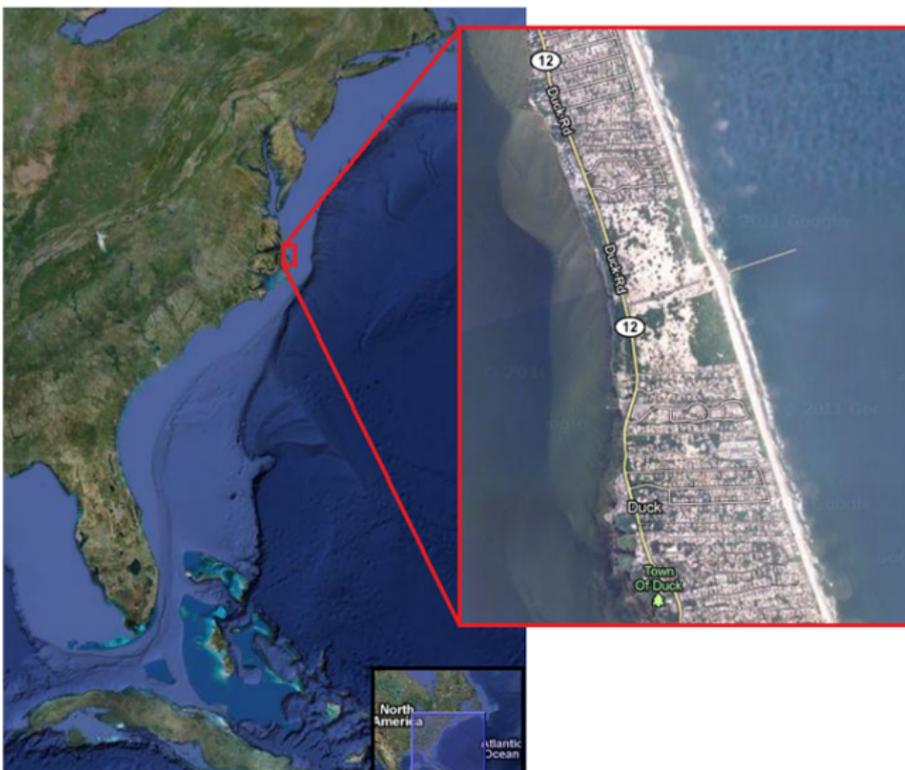

- ▶ Field measurements with 34 mins sample duration
- ▶ Wave height probability distribution
 - ▶ Zero-crossings and ranking wave heights
- ▶ Evolution of frequency spectrum
 - ▶ Welch method for ensemble averaging of spectrum
- ▶ Infragravity wave prediction
 - ▶ Run Ideal Surf Beat (IDSB) model

Summary of Conclusions

- ▶ Wave height distribution
 - ▶ Performed a Kolmogorov-Smirnov test on 1442 individual sea states
 - ▶ Glukovskiy distribution (as formulated by van Vledder, 1991) provided best fit to data
- ▶ Evolution of frequency spectrum
 - ▶ TMA spectrum was not comparable with the field measurements, especially for low frequencies
 - ▶ Greater attenuation with larger spectral density for all ranges of kd
- ▶ Infragravity wave prediction
 - ▶ Ideal Surf Beat (IDSB) model has an average skill of 78%

Field Measurements: Location

- ▶ Duck, North Carolina, USA

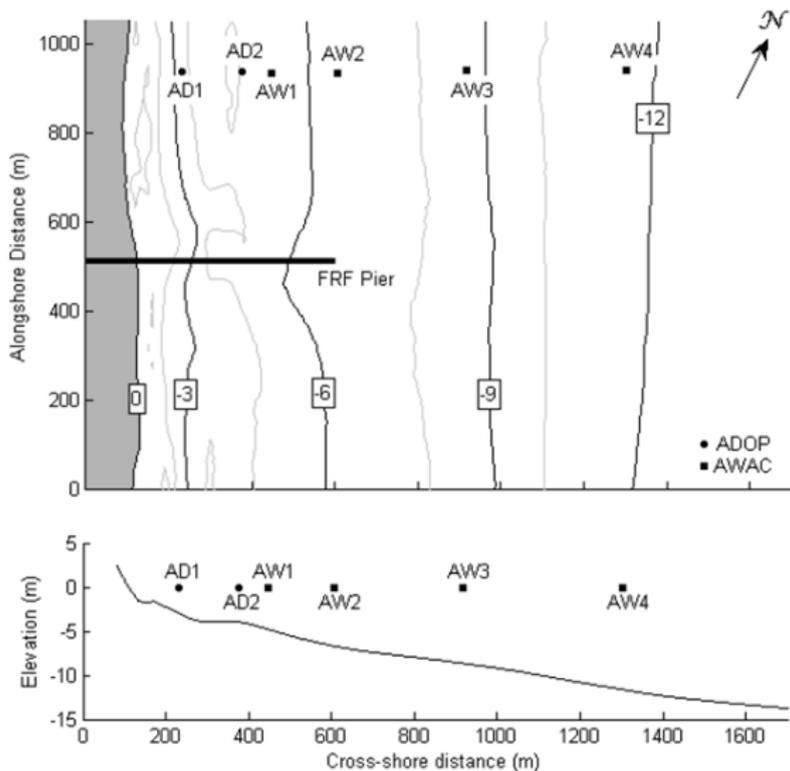

Field Measurements: Cases Examined

- ▶ Instruments
 - ▶ Nortek Aquadopp (ADOP)
 - ▶ Nortek Acoustic Wave And Current (AWAC) meters
 - ▶ Sample at 2 Hz for 34 mins every hour
- ▶ Data available for 1442 sea states in 5 storm events

Case	Date	Max. H_s [m]	Mean T_p [s]
E1	01–05 September 2010	3.2	12.3
E2	21–23 August 2009	3.3	15.1
E3	11–16 November 2009	3.0	12.0
E6	26–28 March 2009	2.9	13.6
E8	29–30 August 2010	1.7	12.7

- ▶ Case E2 corresponds to Hurricane Bill

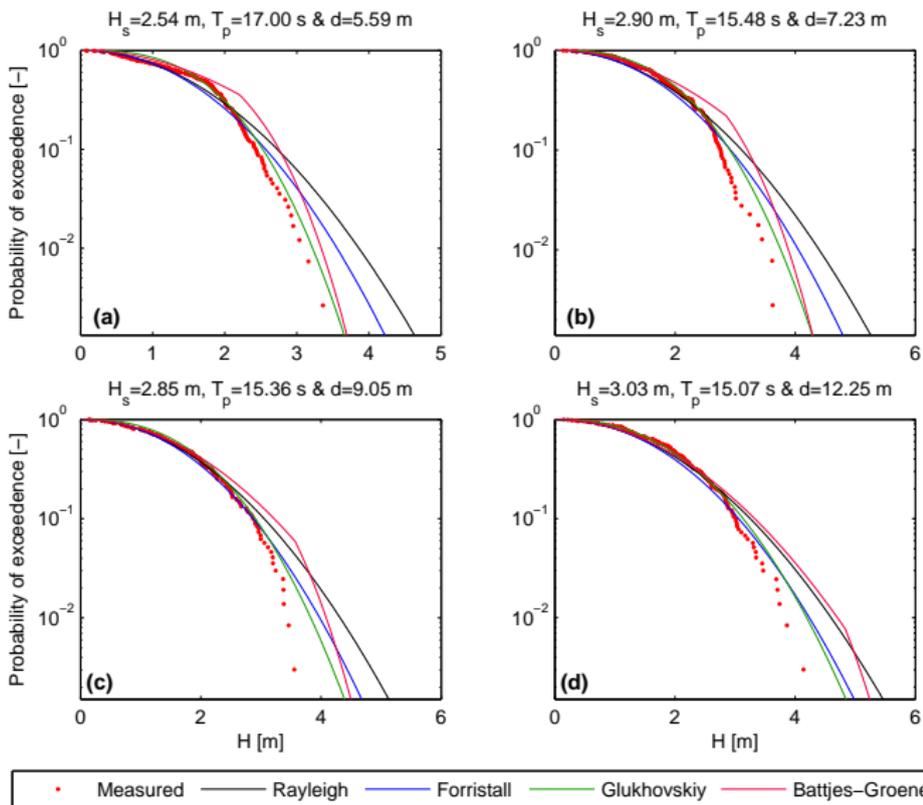

Field Measurements: Bathymetry

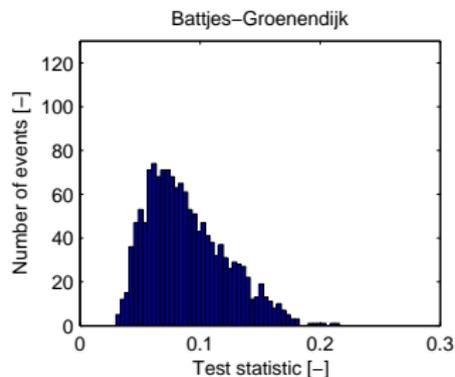

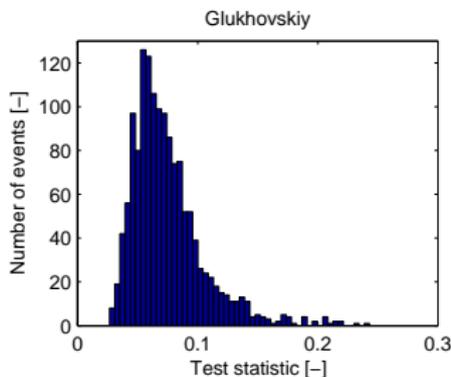

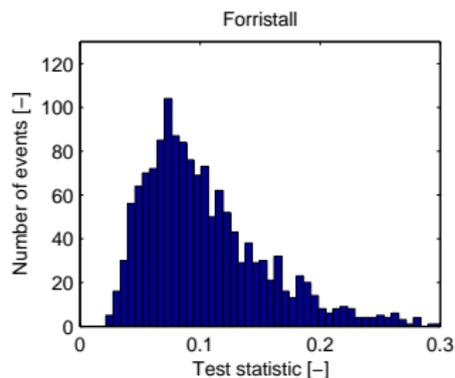

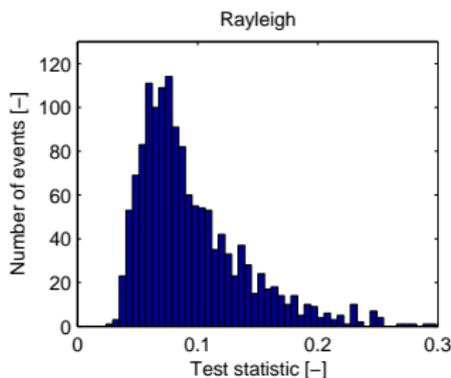

Wave Height Distribution

- ▶ Theoretical distributions
 1. Rayleigh: $f(H_s)$
 2. Forristall (1978): $f(H_s)$
 3. Glukhovskiy (formulation of van Vledder, 1991): $f(H_s, d)$
 4. Battjes and Groenendijk (2000): $f(H_s, d, \alpha)$
- ▶ Distributions 1 and 2 are for deep water
- ▶ Distributions 3 and 4 were developed specifically for shallow water
- ▶ Battjes-Groenendijk distribution is a composite Weibull in 2 parts
- ▶ None of the distributions has an upper limit
- ▶ Analysis
 - ▶ Visual inspection for individual sea states
 - ▶ Kolmogorov-Smirnov test for goodness of fit

Example Probability Distributions for Individual Sea States

Test Statistic from K-S Test: Histograms

Test Statistic from K-S Test: Summary

- ▶ Summary of test statistic, k^*

Distribution	Mean k^*	Mode k^*	Median k^*	Std k^*	Pass [%]
Rayleigh	0.094	0.059	0.082	0.044	87
Forristall	0.104	0.091	0.092	0.051	80
Glukovskiy	0.075	0.063	0.069	0.030	96
Battjes-Gronendijk	0.089	0.059	0.084	0.033	91

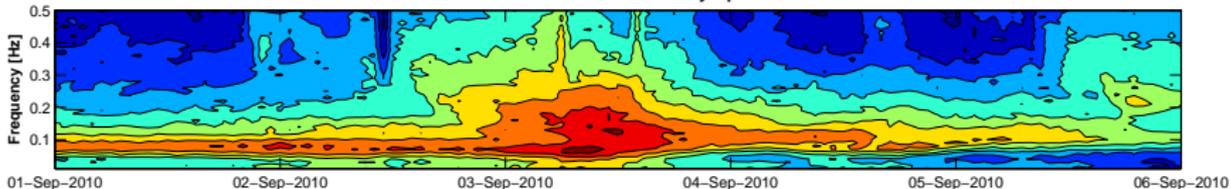

- ▶ Glukhovskiy has the best agreement with the field measurements

Evolution of Frequency Spectrum

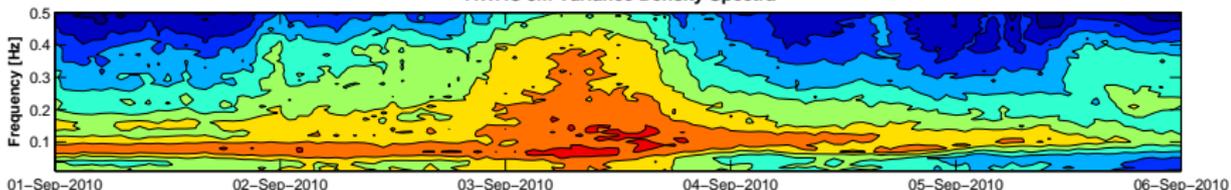

- ▶ Frequency resolution of 0.01 Hz
- ▶ Analyse spectral evolution of the frequency variance density spectra in time and space
- ▶ Focus on difference between spectra at 11 m & 5 m AWACs
- ▶ Calculate the gain between the two spectra
- ▶ Compare gain to TMA transfer function

Evolution of Spectrum & Gain

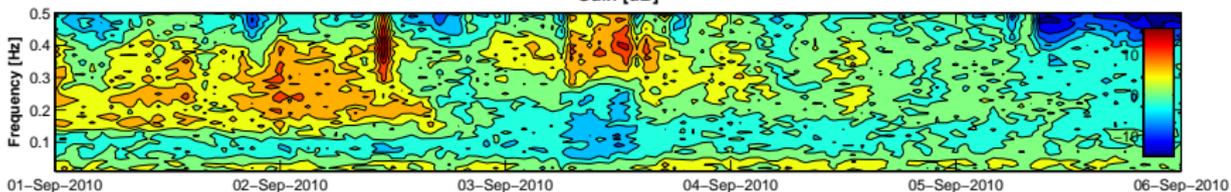

AWAC 11m Variance Density Spectra

AWAC 5m Variance Density Spectra

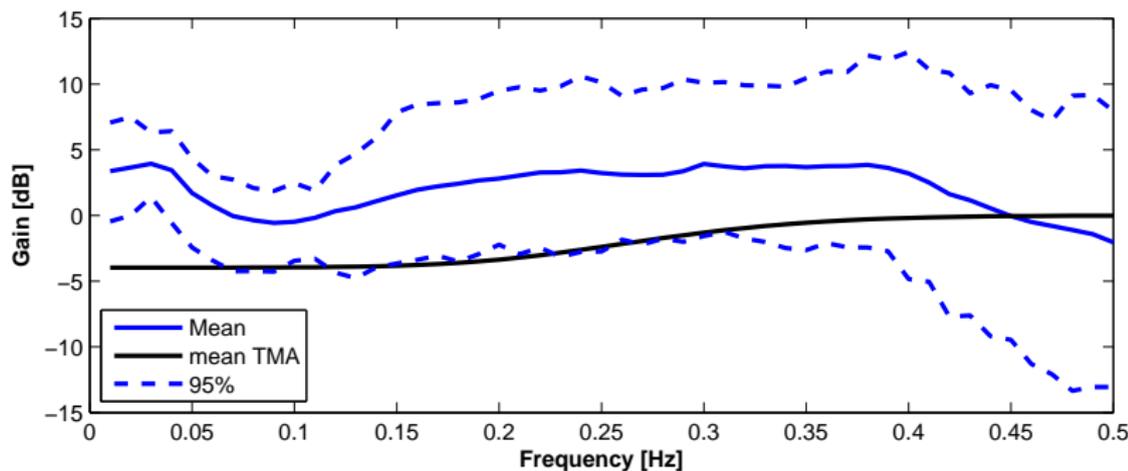

Gain [dB]

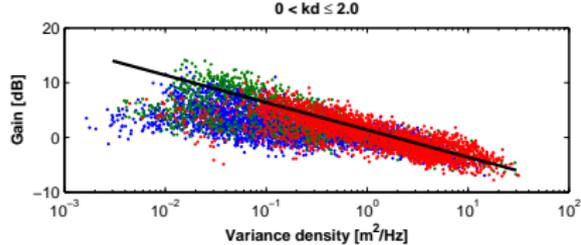

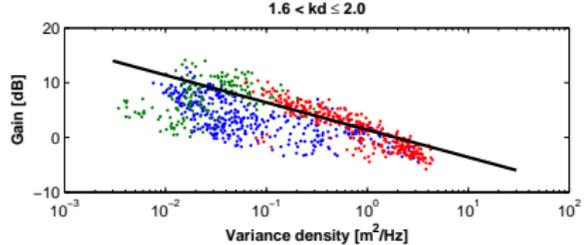

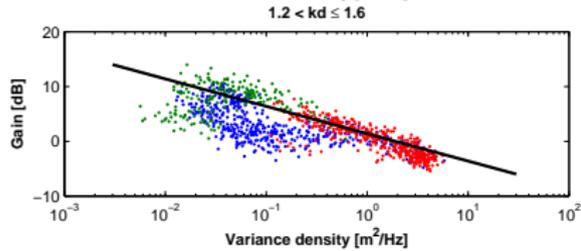

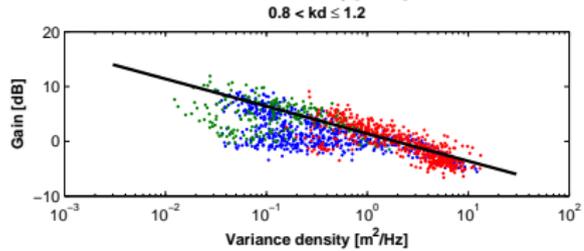

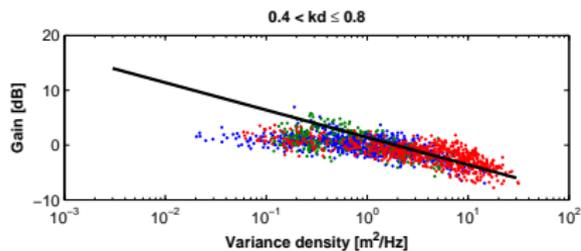

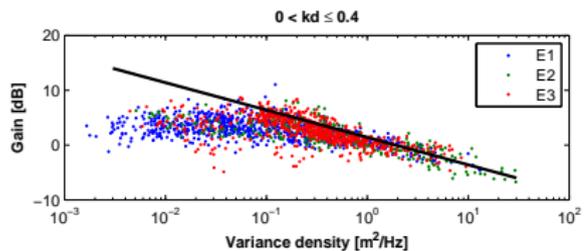

Mean Gain

- ▶ Calculate difference between frequency spectrum at 11 m and 5 m
- ▶ Take the mean of this difference
- ▶ Compare to TMA transfer function between 11 m and 5 m

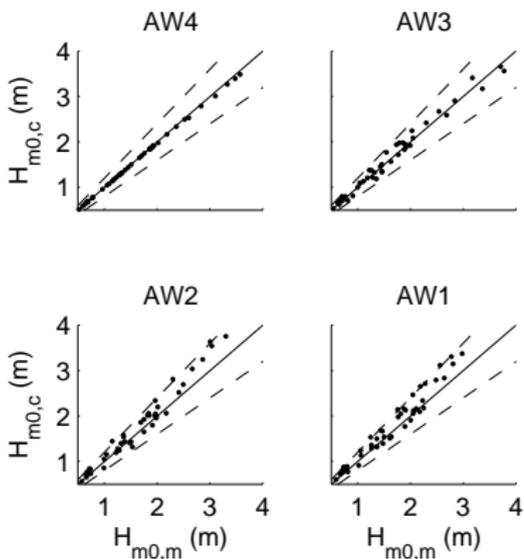

Attenuation

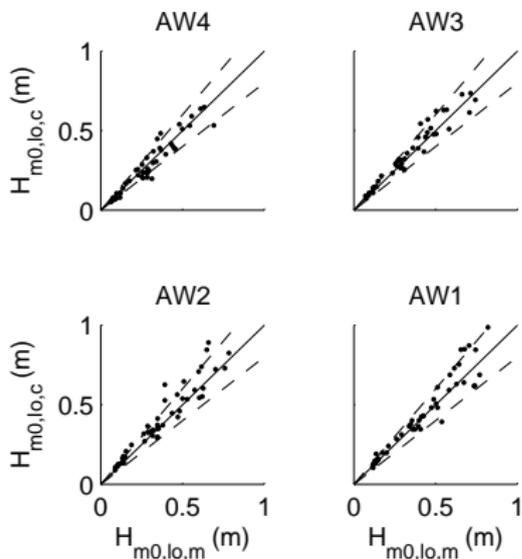

Ideal Surf Beat (IDSB) Model

- ▶ Infragravity waves have period between 20 s & 200 s
- ▶ IDSB can simulate generation of bound and free infragravity waves
 - ▶ Reniers *et al.* (2002) JGR
- ▶ Assumptions
 - ▶ Linear shallow-water wave model
 - ▶ Constant along shore bathymetry
 - ▶ Full reflection of IG waves at shoreline
 - ▶ Narrow spectrum in both frequency and direction
- ▶ Incoming and outgoing waves
 - ▶ Incoming directionally-spread short waves
 - ▶ Incoming *bound* IG waves
 - ▶ Outgoing trapped and leaky *free* IG waves

Calculated vs Measured: Case E2

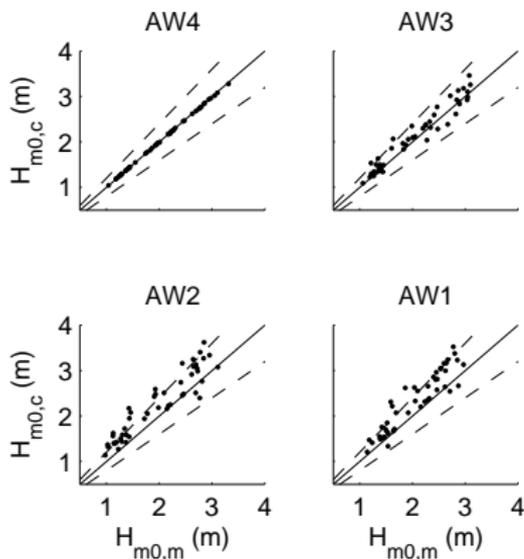

(a) Short waves

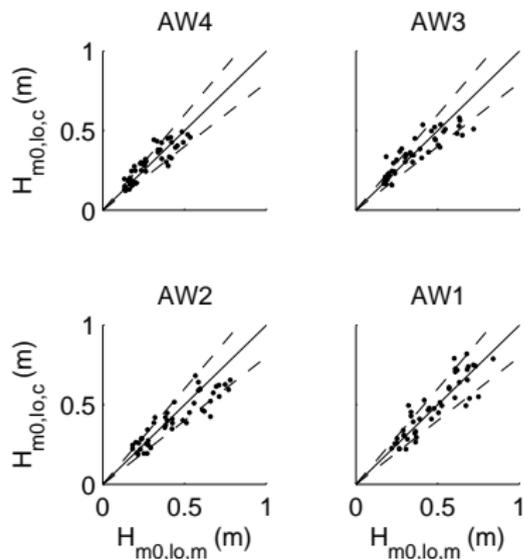

(b) Infragravity waves

Calculated vs Measured: Case E6

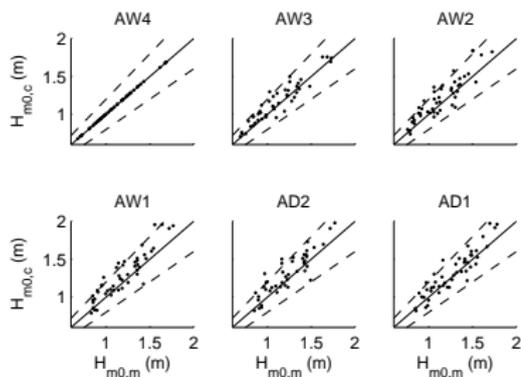

(c) Short waves

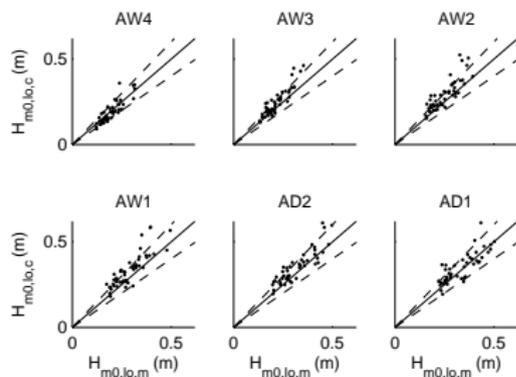

(d) Infragravity waves

Calculated vs Measured: Case E8

(e) Short waves

(f) Infragravity waves

Calculated vs Measured: Table

- Determine the skill, s , at each instrument and overall

$$s = 1 - \frac{\sqrt{\langle (H_{rms,m} - H_{rms,c})^2 \rangle}}{\langle H_{rms,m}^2 \rangle}$$

Case	AW4	AW3	AW2	AW1	AD2	AD1	Overall
E2	0.78	0.83	0.78	0.73	-	-	0.78
E6	0.78	0.75	0.74	0.81	-	-	0.77
E8	0.83	0.78	0.74	0.75	0.8	0.81	0.79

- Average skill of 78%

Conclusions

- ▶ Analysed new shallow water measurements at FRF
 - ▶ Data available for 1442 sea states in 5 storm events
- ▶ Wave height distribution
 - ▶ Performed a Kolmogorov-Smirnov test on every sea state
 - ▶ Glukovskiy distribution (as formulated by van Vledder, 1991) provided best fit to data
- ▶ Evolution of frequency spectrum
 - ▶ TMA spectrum was not comparable with the field measurements, especially for low frequencies
 - ▶ Greater attenuation with larger spectral density for all ranges of kd
- ▶ Simulating infragravity waves with Ideal Surf Beat (IDSB) model
 - ▶ Average skill of 78%
